Chapter 8
Technicalities: Functions, etc.

Bjarne Stroustrup

www.stroustrup.com/Programming
Abstract

- This lecture and the following present some technical details of the language to give a slightly broader view of C++’s basic facilities and to provide a more systematic view of those facilities. This also acts as a review of many of the notions presented so far, such as types, functions, and initialization, and provides an opportunity to explore our tool without adding new programming techniques or concepts.
Overview

- Language Technicalities
- Declarations
  - Definitions
  - Headers and the preprocessor
  - Scope
- Functions
  - Declarations and definitions
  - Arguments
  - Call by value, reference, and const reference
- Namespaces
  - “Using” declarations
Language technicalities

- Are a necessary evil
  - A programming language is a foreign language
  - When learning a foreign language, you have to look at the grammar and vocabulary
  - We will do this in this chapter and the next

- Because:
  - Programs must be precisely and completely specified
    - A computer is a very stupid (though very fast) machine
    - A computer can’t guess what you “really meant to say” (and shouldn’t try to)
  - So we must know the rules
    - Some of them (the C++11 standard is 1,310 pages)

- However, never forget that
  - What we study is programming
  - Our output is programs/systems
  - A programming language is only a tool
Technicalities

- Don’t spend your time on minor syntax and semantic issues. There is more than one way to say everything
  - Just like in English
- Most design and programming concepts are universal, or at least very widely supported by popular programming languages
  - So what you learn using C++ you can use with many other languages
- Language technicalities are specific to a given language
  - But many of the technicalities from C++ presented here have obvious counterparts in C, Java, C#, etc.
Declarations

- A declaration introduces a name into a scope.
- A declaration also specifies a type for the named object.
- Sometimes a declaration includes an initializer.
- A name must be declared before it can be used in a C++ program.

Examples:

- `int a = 7;`  // an int variable named ‘a’ is declared
- `const double cd = 8.7;`  // a double-precision floating-point constant
- `double sqrt(double);`  // a function taking a double argument and
  // returning a double result
- `vector<Token> v;`  // a vector variable of Tokens (variable)
Declarations are frequently introduced into a program through “headers”
- A header is a file containing declarations providing an interface to other parts of a program

This allows for abstraction – you don’t have to know the details of a function like `cout` in order to use it. When you add

```cpp
#include "std_lib_facilities.h"
```

to your code, the declarations in the file `std_lib_facilities.h` become available (including `cout`, etc.).
For example

- **At least three errors:**
  ```cpp
  int main()
  {
      cout << f(i) << 'n';
  }
  ```

- **Add declarations:**
  ```cpp
  #include "std_lib_facilities.h"  // we find the declaration of cout in here
  int main()
  {
      cout << f(i) << 'n';
  }
  ```
For example

- Define your own functions and variables:

```cpp
#include "std_lib_facilities.h" // we find the declaration of cout in here

int f(int x) { /* ... */ } // declaration of f

int main()
{
    int i = 7; // declaration of i
    cout << f(i) << 'n';
}
```
Definitions

A declaration that (also) fully specifies the entity declared is called a definition

- **Examples**
  - `int a = 7;`
  - `int b; // an (uninitialized) int`
  - `vector<double> v; // an empty vector of doubles`
  - `double sqrt(double) { ... }; // a function with a body`
  - `struct Point { int x; int y; };`

- **Examples of declarations that are not definitions**
  - `double sqrt(double); // function body missing`
  - `struct Point; // class members specified elsewhere`
  - `extern int a; // extern means “not definition”`
  - `// “extern” is archaic; we will hardly use it`
Declarations and definitions

- You can’t *define* something twice
  - A definition says what something is
  - Examples
    ```c
    int a;   // definition
    int a;   // error: double definition
    double sqrt(double d) { … }  // definition
    double sqrt(double d) { … }  // error: double definition
    ```

- You can *declare* something twice
  - A declaration says how something can be used
    ```c
    int a = 7;   // definition (also a declaration)
    extern int a; // declaration
    double sqrt(double); // declaration
    double sqrt(double d) { … } // definition (also a declaration)
    ```
Why both declarations and definitions?

- To refer to something, we need (only) its declaration
- Often we want the definition “elsewhere”
  - Later in a file
  - In another file
    - preferably written by someone else
- Declarations are used to specify interfaces
  - To your own code
  - To libraries
    - Libraries are key: we can’t write all ourselves, and wouldn’t want to
- In larger programs
  - Place all declarations in header files to ease sharing
Kinds of declarations

- The most interesting are
  - Variables
    - `int x;`
    - `vector<int> vi2 {1,2,3,4};`
  - Constants
    - `void f(const X&);`
    - `constexpr int = isqrt(2);`
  - Functions (see §8.5)
    - `double sqrt(double d) { /* ... */ }`
  - Namespaces (see §8.7)
  - Types (classes and enumerations; see Chapter 9)
  - Templates (see Chapter 19)
Header Files and the Preprocessor

- A header is a file that holds declarations of functions, types, constants, and other program components.
- The construct

\[
\text{#include "std\_lib\_facilities.h"}
\]

is a “preprocessor directive” that adds declarations to your program.
- Typically, the header file is simply a text (source code) file.
- A header gives you access to functions, types, etc. that you want to use in your programs.
  - Usually, you don’t really care about how they are written.
  - The actual functions, types, etc. are defined in other source code files.
    - Often as part of libraries.
A header file (here, `token.h`) defines an interface between user code and implementation code (usually in a library).

The same `#include` declarations in both `.cpp` files (definitions and uses) ease consistency checking.
Scope

- A scope is a region of program text
  - Global scope (outside any language construct)
  - Class scope (within a class)
  - Local scope (between `{ … }` braces)
  - Statement scope (e.g. in a for-statement)

- A name in a scope can be seen from within its scope and within scopes nested within that scope
  - Only after the declaration of the name ("can’t look ahead" rule)
  - Class members can be used within the class before they are declared

- A scope keeps “things” local
  - Prevents my variables, functions, etc., from interfering with yours
  - Remember: real programs have many thousands of entities
  - Locality is good!
    - Keep names as local as possible
Scope

#include "std_lib_facilities.h"  // get max and abs from here

// no r, i, or v here

class My_vector {

  vector<int> v;                 // v is in class scope

public:

  int largest()    // largest is in class scope
  {
    int r = 0;        // r is local
    for (int i = 0; i<v.size(); ++i) // i is in statement scope
      r = max(r,abs(v[i]));
    // no i here
    return r;
  } // no r here

}; // no v here

// no v here
Scopes nest

int x;  // global variable – avoid those where you can
int y;  // another global variable

int f()
{
    int x;  // local variable (Note – now there are two x’s)
    x = 7;   // local x, not the global x
    {
        int x = y;  // another local x, initialized by the global y
        // (Now there are three x’s)
        ++x;  // increment the local x in this scope
    }
}

// avoid such complicated nesting and hiding: keep it simple!
Recap: Why functions?

- Chop a program into manageable pieces
  - “divide and conquer”
- Match our understanding of the problem domain
  - Name logical operations
  - A function should do one thing well
- Functions make the program easier to read
- A function can be useful in many places in a program
- Ease testing, distribution of labor, and maintenance
- Keep functions small
  - Easier to understand, specify, and debug
Functions

- General form:
  - `return_type name (formal arguments);` // a declaration
  - `return_type name (formal arguments) body` // a definition
  - For example
    ```
    double f(int a, double d) { return a*d; }
    ```
- Formal arguments are often called parameters
- If you don’t want to return a value give `void` as the return type
  ```
  void increase_power(int level);
  ```
  - Here, `void` means “doesn’t return a value”
- A body is a block or a try block
  ```
  { /* code */ } // a block
  try { /* code */ } catch(exception& e) { /* code */ } // a try block
  ```
- Functions represent/implement computations/calculations
// call-by-value (send the function a copy of the argument’s value)
int f(int a) { a = a+1; return a; }

int main()
{
    int xx = 0;
    cout << f(xx) << 'n'; // writes 1
    cout << xx << 'n';    // writes 0; f() doesn’t change xx
    int yy = 7;
    cout << f(yy) << 'n'; // writes 8; f() doesn’t change yy
    cout << yy << 'n';    // writes 7
}

a: 0
copy the value

xx: 0

a: 7
copy the value

yy: 7
Functions: Call by Reference

// call-by-reference (pass a reference to the argument)
int f(int& a) { a = a+1; return a; }

int main()
{
    int xx = 0;
    cout << f(xx) << 'n'; // writes 1
    // f() changed the value of xx
    cout << xx << 'n'; // writes 1
    int yy = 7;
    cout << f(yy) << 'n'; // writes 8
    // f() changes the value of yy
    cout << yy << 'n'; // writes 8
}
Avoid (non-const) reference arguments when you can

- They can lead to obscure bugs when you forget which arguments can be changed

```cpp
int incr1(int a) { return a+1; }
void incr2(int& a) { ++a; }
int x = 7;
x = incr1(x); // pretty obvious
incr2(x);   // pretty obscure
```

So why have reference arguments?

- Occasionally, they are essential
  - *E.g.*, for changing several values
  - For manipulating containers (*e.g.*, vector)
- `const` reference arguments are very often useful
Call by value/by reference/by const-reference

void f(int a, int& r, const int& cr) { ++a; ++r; ++cr; } // error: cr is const
void g(int a, int& r, const int& cr) { ++a; ++r; int x = cr; ++x; } // ok

int main()
{
    int x = 0;
    int y = 0;
    int z = 0;
    g(x,y,z);   // x==0; y==1; z==0
    g(1,2,3);   // error: reference argument r needs a variable to refer to
    g(1,y,3);   // ok: since cr is const we can pass “a temporary”
}

// const references are very useful for passing large objects
References

- “reference” is a general concept
  - Not just for call-by-reference

```cpp
int i = 7;
ext i = 7;
int& r = i;
const int& cr = i;
// cr = 7; // error: cr refers to const
i = 8;
// write out the value of i (that’s 8)
```

- You can
  - think of a reference as an alternative name for an object

- You can’t
  - modify an object through a `const` reference
  - make a reference refer to another object after initialization
For example

- A range-for loop:
  - `for (string s : v) cout << s << "\n";`  // s is a copy of some v[i]
  - `for (string& s : v) cout << s << "\n";`  // no copy
  - `for (const string& s : v) cout << s << "\n";`  // and we don’t modify v
Compile-time functions

You can define functions that *can be* evaluated at compile time:

**constexpr** functions

```cpp
constexpr double xscale = 10; // scaling factors
constexpr double yscale = .8;

constexpr Point scale(Point p) { return {xscale*p.x,yscale*p.y}; };

constexpr Point x = scale({123,456}); // evaluated at compile time
```

```cpp
void use(Point p)
{
 constexpr Point x1 = scale(p); // error: compile-time evaluation
 // requested for variable argument
 Point x2 = scale(p);  // OK: run-time evaluation
}
```
Guidance for Passing Variables

- Use call-by-value for very small objects
- Use call-by-const-reference for large objects
- Use call-by-reference only when you have to
- Return a result rather than modify an object through a reference argument

For example

class Image { /* objects are potentially huge */ };  
void f(Image i); ... f(my_image); // oops: this could be s-l-o-o-o-w  
void f(Image& i); ... f(my_image); // no copy, but f() can modify my_image  
void f(const Image&); ... f(my_image); // f() won’t mess with my_image  
Image make_image(); // most likely fast! (“move semantics” – later)
Namespaces

- Consider this code from two programmers Jack and Jill

```cpp
class Glob { /* ... */ }; // in Jack’s header file jack.h
class Widget { /* ... */ }; // also in jack.h
class Blob { /* ... */ }; // in Jill’s header file jill.h
class Widget { /* ... */ }; // also in jill.h

#include "jack.h"; // this is in your code
#include "jill.h"; // so is this

void my_func(Widget p) // oops! – error: multiple definitions of Widget
{
  // ...
}
```
Namespaces

The compiler will not compile multiple definitions; such clashes can occur from multiple headers.

One way to prevent this problem is with namespaces:

```cpp
namespace Jack {
    // in Jack's header file
    class Glob { /* */ };
    class Widget { /* */ };
}

#include "jack.h"; // this is in your code
#include "jill.h"; // so is this

void my_func(Jack::Widget p) // OK, Jack's Widget class will not
// clash with a different Widget
{ // ...
}
```
Namespaces

- A namespace is a named scope
- The :: syntax is used to specify which namespace you are using and which (of many possible) objects of the same name you are referring to
- For example, `cout` is in namespace `std`, you could write:

  ```
  std::cout << "Please enter stuff... \n";
  ```
using Declarations and Directives

- To avoid the tedium of
  - `std::cout << "Please enter stuff… \n";`

  you could write a “using declaration”
  - `using std::cout; // when I say cout, I mean std::cout`
  - `cout << "Please enter stuff… \n"; // ok: std::cout`
  - `cin >> x; // error: cin not in scope`

- or you could write a “using directive”
  - `using namespace std; // “make all names from namespace std available”`
  - `cout << "Please enter stuff… \n"; // ok: std::cout`
  - `cin >> x; // ok: std::cin`

- More about header files in chapter 12
Next talk

- More technicalities, mostly related to classes
